THE NON-ABELIAN TENSOR SQUARE AND SCHUR MULTIPLIER OF
GROUPS OF ORDERS $p^2q$, $pq^2$ AND $p^2qr$

S. H. JAFARI, P. NIROOMAND, AND A. ERFANIAN

Abstract. The aim of this paper is to determine the non-abelian tensor square and
Schur multiplier of groups of square free order and of groups of orders $p^2q$, $pq^2$ and $p^2qr$,
where $p$, $q$ and $r$ are primes and $p < q < r$.

1. Introduction

The notion of non-abelian tensor product $G \otimes H$ of groups $G$ and $H$ which was introduced
by R. Brown and J.-L. Loday [1, 2] is a generalization of the usual tensor product of the
abelianized groups, on the assumption that each of $G$ and $H$ acts on the other. Specially,
for given groups $G$, $H$ each of which acts on the other

\[ G \times H \rightarrow G, (g, h) \mapsto h^g ; \quad H \times G \rightarrow G, (h, g) \mapsto g^h \]

in such a way that for all $g, g_1 \in G$ and $h, h_1 \in H$,

\[ g_1 h = g_1^{-1} (h^{g_1} g) \quad \text{and} \quad h_1 g h = h_1^{-1} (g^{h_1} h), \quad (*) \]

where $G$ and $H$ acts on themselves by conjugation. Then the non-abelian tensor product
$G \otimes H$ is defined to be the group generated by symbols $g \otimes h$, $g \in G, h \in H$, subject to the
relations

\[ g_1 g \otimes h = (g_1 \otimes g_1) (g_1 \otimes h) \quad , \quad g \otimes h_1 h = (g \otimes h_1) \ (g_1 \otimes h_1) \]

for all $g, g_1 \in G$, $h, h_1 \in H$, where $G$ acts on itself by conjugation, i.e. $g_1 g = g_1 g^{-1}$, and
similarly for $H$. In particular, as the conjugation action of a group $G$ on itself satisfies $(*)$,
the tensor square $G \otimes G$ may always be defined.

Following the publications of Brown and Loday’s work, a number of purely group theoretic
papers have appeared on the topic. Some investigate general structural properties of the
tensor square, while the others are devoted to explicit descriptions for particular groups, for
instance dihedral, quaternionic, symmetric and all groups of order at most 30 in [3].
Later, Hannebauer [6] determined the structure of tensor square of the groups \( SL(2, q) \),
\( PSL(2, q) \), \( GL(2, q) \) and \( PGL(2, q) \) for all \( q \geq 5 \) and \( q \neq 9 \).
Ellis and Leonard [7] devise a computer algorithm for the computation of tensor square of
finite groups which in its applications can handle much larger groups than those given in [3].
Using the CAYLEY-program, they compute the tensor square of \( B(2, 4) \), the 2-generator
Burnside group of exponent 4, where \( |B(2, 4)| = 2^{12} \). Recently, it is also improved for the
groups \( SL(n, q) \), \( PSL(n, q) \), \( GL(n, q) \), \( PGL(n, q) \) for all \( n, q \geq 2 \) in [4] and for extra special
\( p \)-groups (\( p \neq 2 \)) in [5]. These results extremely depend on knowing the order of
\( M(G) \), the Schur multiplier of a group \( G \).
In the present paper, we focus on the non-abelian tensor square of the group of square
free order and groups of orders \( p^2 q \), \( pq^2 \) and \( p^2 qr \), where \( p \), \( q \) and \( r \) are primes and \( p < q < r \).
It should be mentioned, generally finding the structure of \( M(G) \) and \( G \otimes G \) for a class of
groups is not so easy. Although some computations of \( G \otimes G \) for metacyclic and polycyclic
groups have been done in [3, 9] without knowing \( M(G) \). So our result included some special
cases which have been summarized as follows.

**Theorem A.** Let \( G \) be a group of order \( n \), where \( n \) is a square free number. Then

\[ G \otimes G \cong \mathbb{Z}_n. \]

**Theorem B.** Let \( G \) be a group of order \( p^2 q \), where \( p \) and \( q \) are prime numbers and
\( p < q \). The structure of \( G \otimes G \) is one of the following

(i) If \( G^{ab} = \mathbb{Z}_{p^2} \), then \( G \otimes G \cong \mathbb{Z}_{p^2 q} \).

(ii) If \( G^{ab} = \mathbb{Z}_p \times \mathbb{Z}_p \), then \( G \otimes G \cong (\mathbb{Z}_p)^4 \times \mathbb{Z}_q \).

(iii) If \( G^{ab} = \mathbb{Z}_3 \), then \( G \otimes G \cong \mathbb{Z}_3 \times Q_2 \), in which \( Q_2 \) is the quaternion group of order 8.

**Theorem C.** Let \( G \) be a group of order \( pq^2 \), where \( p \) and \( q \) are prime numbers and \( p < q \).
The structure of \( G \otimes G \) is one of the following
(i) If $G' = Z_{q^2}$, then $G \otimes G \cong Z_{pq^2}$.

(ii) If $G' = Z_q \times Z_q$ and $M(G) = 0$ or if $G' = Z_q$, then $G \otimes G \cong Z_p \times (Z_q)^2$.

(iii) If $G' = Z_q \times Z_q$ and $M(G) = Z_q$, then $G \otimes G \cong Z_p \times H$, where $H$ is an extra special $q$-group of order $q^3$.

**Theorem D.** Let $G$ be a group of order $p^2qr$, where $p$, $q$ and $r$ are prime numbers $p < q < r$, $pq \neq 6$. The structure of $G \otimes G$ is one of the following:

(i) If $|G'| = q$, $r$ or $qr$ ($q \nmid r - 1$), then $G \otimes G \cong Z_{p^2qr}$ when $G^{ab}$ is cyclic, otherwise $G \otimes G \cong (Z_p)^4 \times Z_{qr}$.

(ii) If $|G'| = qr$ ($q \mid r - 1$), then $G \otimes G \cong Z_{p^2r} \times G'$ when $G^{ab}$ is cyclic, otherwise $G \otimes G \cong (Z_p)^4 \times G'$.

2. Basic Results

In this section, we recall some definitions and basic results on the tensor square which are necessary for our main theorems.

Let $G$ be a group and $G \otimes G$ be the tensor square of $G$. The exterior square $G \wedge G$ is obtained by imposing the additional relation $g \otimes g = 1$ ($g \in G$) on $G \otimes G$. Moreover, we denote by $\nabla(G)$ as the subgroup generated by all elements $g \otimes g$. The commutator map induces homomorphisms $\kappa : G \otimes G \rightarrow G$, and $\kappa' : G \wedge G \rightarrow G$ sending $g \otimes h$ and $g \wedge h$ to $[g, h] = ghg^{-1}h^{-1}$, denoted ker $\kappa$ by $J_2(G)$.

Results in Brown, Loday [1 2] give the following commutative diagram with exact rows and central extensions as columns

\[
\begin{array}{ccccccccc}
0 & 0 & \\
\downarrow & & \\
\Gamma(G^{ab}) & \rightarrow & J_2(G) & \rightarrow & M(G) & \rightarrow & 0 & \\
| & & \downarrow & & \downarrow & & \downarrow & & \\
\Gamma(G^{ab}) & \rightarrow & G \otimes G & \rightarrow & G \wedge G & \rightarrow & 1 & \\
& & \kappa \downarrow & & \kappa' \downarrow & & \\
& & G' & \rightarrow & G' & & \\
& & 1 & \rightarrow & 1 & &
\end{array}
\]
where $\Gamma$ is the Whitehead’s quadratic functor (see Whitehead [10]).

Now let us remind the following theorems which play an important role in the proof of the main theorems.

**Theorem 2.1.** [3, Proposition 8]. If $G$ is a group in which $G'$ has a cyclic complement $C$, then $G \otimes G \cong (G \wedge G) \times G^{ab}$ and hence $|G \otimes G| = |G||M(G)|$.

**Theorem 2.2.** [5, Theorem A]. Let $G$ be a group such that $G^{ab} = \prod_{i=1}^{n} \prod_{j=1}^{k_i} \mathbb{Z}_{p_i^{e_{ij}}}$, where $1 \leq e_{i1} \leq e_{i2} \leq \ldots \leq e_{ik_i}$ for all $1 \leq i \leq n$, $k_i \in \mathbb{N}$ and $p_i \neq 2$. Then

$$|G \otimes G| = \prod_{i=1}^{n} p_i^{d_i} |G||M(G)|$$

in which $d_i = \sum_{j=1}^{k_i} (k_i - j)e_{ij}$.

3. Proof of Main Theorems

In this section we prove the main theorem as we mentioned earlier in section one.

**Lemma 3.1.** Let $G$ be a finite non-abelian group.

(i) If $G$ is a square free order group, then $G'$ is cyclic.

(ii) If $G$ is a group of order $p^2q$, then $G' = \mathbb{Z}_q$ or $G' = \mathbb{Z}_2 \times \mathbb{Z}_2$.

(iii) If $G$ is a group of order $pq^2$, then $G' = \mathbb{Z}_q$ or $G' = \mathbb{Z}_{q^2}$ or $G' = \mathbb{Z}_q \times \mathbb{Z}_q$.

(iv) If $G$ is a group of order $p^2qr$ and $pq \neq 6$, then $|G'| = q, r$ or $qr$.

(v) If $G$ is a group of order $p^2qr$ and $pq = 6$, then $|G'| = 3, r, 3r, 4$ or $4r$.

**Proof.** One may use sylow theorems for examples in case (ii) to show the number of $p$-sylow subgroups of $G$ is 1 or $q$ and the number of $q$-sylow subgroups of $G$ is 1 or $p^2$. If $G$ has one $q$-sylow subgroup $Q$, then $G/Q$ is abelian and so $G' = \mathbb{Z}_q$. Otherwise $p = 2$ and $q = 3$, hence $|G| = 12$ and we should have $G \cong A_4$.

The proof of other cases is similar and we omit it.
Lemma 3.2. Let $G$ be a finite non-abelian group.

(i) If $G$ is a square free order group, then $M(G) = 0$.

(ii) If $G$ is a group of order $p^2q$, then

$$M(G) = \begin{cases} 
0 & \text{if } G' = \mathbb{Z}_q \text{ and } G^{ab} = \mathbb{Z}_{p^2} \\
\mathbb{Z}_p & \text{if } G' = \mathbb{Z}_q \text{ and } G^{ab} = \mathbb{Z}_p \times \mathbb{Z}_p \\
\mathbb{Z}_2 & \text{if } G' = \mathbb{Z}_2 \times \mathbb{Z}_2
\end{cases}$$

(iii) If $G$ is a group of order $pq^2$, then

$$M(G) = \begin{cases} 
0 & \text{if } G' = \mathbb{Z}_q \\
0 & \text{if } G' = \mathbb{Z}_{q^2} \\
0 \text{ or } \mathbb{Z}_q & \text{if } G' = \mathbb{Z}_q \times \mathbb{Z}_q
\end{cases}$$

(iv) If $G$ is a group of order $p^2qr$ and $pq \neq 6$, then

$$M(G) = \begin{cases} 
0 & \text{if } G^{ab} \text{ is cyclic} \\
\mathbb{Z}_p & \text{Otherwise}
\end{cases}$$

(v) If $G$ is a group of order $p^2qr$ and $pq = 6$, then $M(G)$ is as the same as part (iv). Moreover if $|G'| = 4$ or $4r$, then $M(G) = \mathbb{Z}_2$.

Proof. (i) Since all Sylow subgroups of $G$ are cyclic, so $M(G) = 0$. For (ii), if $G' = \mathbb{Z}_q$ and $G^{ab} = \mathbb{Z}_{p^2}$, then again all Sylow subgroups of $G$ are cyclic and therefore $M(G) = 0$.

In the case $G' = \mathbb{Z}_q$ and $G^{ab} = \mathbb{Z}_p \times \mathbb{Z}_p$, we can see that $|G'|$ and $|G^{ab}|$ are coprime, so by Schur-Zassenhaus Lemma, $G'$ has a complement. The result follows from [8, Corollary 2.2.6].

The proof of the other parts is similar. \qed

Lemma 3.3. Let $G$ be a finite non-abelian group.

(i) If $G$ is a square free order group of order $n$, then $|G \otimes G| = n$. 

(ii) If $G$ is a group of order $p^2q$, then

$$|G \otimes G| = \begin{cases} p^2q & \text{if } G^{ab} = \mathbb{Z}_{p^2} \\ p^4q & \text{if } G^{ab} = \mathbb{Z}_p \times \mathbb{Z}_p \\ 24 & \text{if } G^{ab} = \mathbb{Z}_3 \end{cases}$$

(iii) If $G$ is a group of order $pq^2$, then

$$|G \otimes G| = \begin{cases} pq^2 & \text{if } G' = \mathbb{Z}_{q^2} \\ pq^2 & \text{if } G' = \mathbb{Z}_q \text{ or } G' = \mathbb{Z}_q \times \mathbb{Z}_q \text{ and } M(G) = 0 \\ pq^3 & \text{if } G' = \mathbb{Z}_q \times \mathbb{Z}_q \text{ and } M(G) = \mathbb{Z}_q \end{cases}$$

(iv) If $G$ is a group of order $p^2qr$ and $pq \neq 6$, then

$$|G \otimes G| = \begin{cases} p^2qr & \text{if } G^{ab} \text{ is cyclic} \\ p^4qr & \text{Otherwise} \end{cases}$$

(v) If $G$ is a group of order $p^2qr$ and $pq = 6$, then the order of $G \otimes G$ is similar to the part (iv). Moreover if $|G'| = 4$ or $4r$, then $|G \otimes G| = 24r$.

Proof. (i) Since $|G'|$ and $|G^{ab}|$ are coprime, $G'$ has a cyclic complement and $|G \otimes G| = |G|$ by Schur-Zassenhaus Lemma, Theorem 2.1 and Lemma 3.2.

(ii) Suppose that $G^{ab} = \mathbb{Z}_{p^2}$. In this case $|G'|$ and $|G^{ab}|$ are coprime and $|G \otimes G| = |G| = p^2q$ by Lemma 3.2.

Now assume that $G^{ab} = \mathbb{Z}_p \times \mathbb{Z}_p$, if $p \neq 2$, then $|G \otimes G| = p^4q$ by Theorem 2.2 and Lemma 3.2. Otherwise $e(\nabla(G))$ divides $e(G) = 2q$ and $e(\Gamma(G^{ab})) = 4$. Hence $e(\nabla(G)) = 2$ and $\nabla(G) = \mathbb{Z}_2 \times \mathbb{Z}_2 \times \mathbb{Z}_2$ and it implies that $|G \otimes G| = 2^4q$.

We note that if $G^{ab} = \mathbb{Z}_3$, then $G = A_4$ and this case is computed in [3].

(iii) Suppose that $G'$ is cyclic of order $q^2$, so we have $|G \otimes G| = pq^2$ by Theorem 2.1 and Lemma 3.2. The case that $G' = \mathbb{Z}_q \times \mathbb{Z}_q$ and $M(G) = 0$ holds similarly.

Now if $|G'| = q$ and $p \neq 2$, then $|G \otimes G| = pq^2$ by Theorem 2.2 and Lemma 3.2. Also, it is easy to see that $|G \otimes G| = 2q^2$, if $p = 2$.

(iv) Suppose that $G^{ab}$ is cyclic, so $|G \otimes G| = |G|$ by Theorems 2.1 and Lemma 3.2.
The other case is similar to the case (ii).

(v) It is straightforward.

We are ready to the proof of main theorems, notice that if \( G' \) is cyclic, then \( G \otimes G \) is abelian.

**Proof of Theorem A.** Since \( G \) is a group of square free order, then \( G \otimes G \) is abelian of order \( n \) by Lemmas 3.1 and 3.3.

**Proof of Theorem B.** (i) It is clear that \( G \otimes G \) is an abelian group of order \( p^2q \) by Lemma 3.3. On the other hand \( e(G \otimes G) \) divides \( |G \otimes G| \) and the epimorphism \( \pi : G \otimes G \rightarrow G^{ab} \otimes G^{ab} \) implies that \( e(G \otimes G) = p^2q \). Hence \( G \otimes G \cong \mathbb{Z}_{p^2q} \) as required.

(ii) It is as same as the case (i).

(iii) If \( G' = \mathbb{Z}_2 \times \mathbb{Z}_2 \), then \( G = A_4 \) and one may refer to the Table 1 given in [3].

**Proof of Theorem C.** (i) The exponent of \( G \otimes G \) is equal to \( pq^2 \), so the proof follows by Lemma 3.3.

(ii) Since \( \frac{G \otimes G}{J_2(G)} = G' \) is abelian, we have \( (G \otimes G)' \leq J_2(G) \), where \( |J_2(G)| = p \). In addition the epimorphism \( \pi \) implies that \( (G \otimes G)' \) is in it’s kernel which is of order \( q^2 \), so \( (G \otimes G)' = 1 \).

The result holds by Lemma 3.3 and the fact that \( e(G \otimes G) = pq \).

(iii) It is clear that \( \nabla(G) \) and the \( q \)-sylow subgroup of \( G \otimes G \), say \( H \), are normal. Thus by Lemma 3.3

\[
G \otimes G \cong \nabla(G) \times H,
\]

in which \( \nabla(G) = \mathbb{Z}_p \) and \( H \) is of order \( q^3 \).

**Proof of Theorem D.** (i) If \( G^{ab} \) is cyclic, then the epimorphism \( \pi \) implies that \( e(G \otimes G) = p^2qr \), so the result follows by Lemma 3.3.

If \( G^{ab} \) is not cyclic, the proof is similar.

(ii) Assuming \( G^{ab} = \mathbb{Z}_{p^2} \), then \( |
abla(G)| = |J_2(G)| = p^2 \) and it can be easily seen that \( \text{Ker}\pi \) is isomorphic to \( G' \) and of order \( qr \). Moreover since \( e(G \otimes G) = p^2qr \), Lemma 3.3 implies that

\[
G \otimes G \cong \nabla(G) \times \text{Ker}\pi \cong \nabla(G) \times G' \cong \mathbb{Z}_{p^2} \times G'.
\]
If $G^{ab} = \mathbb{Z}_p \times \mathbb{Z}_p$, then $\varepsilon(G \otimes G) = pqr$, $|J_2(G)| = p^4$ and $\text{Ker}\pi \cong G'$. Therefore Lemma 3.3 deduces that

\[ G \otimes G \cong J_2(G) \times \text{Ker}\pi \cong (\mathbb{Z}_p)^4 \times G'. \]

Finally, we note that in Theorem D, if $pq = 6$, i.e. $|G| = 12r$, then $|G'| = 3, r, 3r, 4$ or $4r$. In the cases that $|G'| = 3, r$ or $3r$, the structure of $G \otimes G$ is similar to Theorem D. In other cases one may show that $G \otimes G \cong \mathbb{Z}_{3r} \times Q_2$, where $Q_2$ is the quaternion group of order 8.
